16. ABSTRACT The report gives a detailed summary of data which were generated during the testing of experimental burners on EPA's Large Watertube Simulator (LWS) test facility. The test data are presented as a series of appendices. Appendix A describes the data quality assurance procedures which were used throughout the various tests. Appendices B and C summarize all the valid data obtained during the testing of the different burners. These data are presented as computer generated lists of all relevant furnace input data and flue gas measurements.

ABSTRACT

This report presents a detailed summary of data which were generated during the testing of experimental burners on the Large Watertube Simulator (LWS) test facility under Environmental Protection Agency Contract No. 68-02-3130.

The test data are presented as a series of Appendices. Appendix A of the report describes the data quality assurance procedures which were employed throughout the various test series. Appendices B and C summarize all the valid data obtained during the testing of the different burners. These data are presented as computer generated listings of all relevant furnace input data and flue gas measurements.

The work described in this report has been supported by the United States Environmental Protection Agency through Contract No. 68-02-3130 to Babcock & Wilcox (B&W) and to Energy and Environmental Research Corporation under subcontract No. 940962 NR.

APPENDIX A

QUALITY ASSURANCE

A.1 Objectives

The success of this program lies in the quality of the data collected. When this program was initiated in 1978, the U.S. Environmental Protection Agency had not yet established requirements for Quality Assurance Plans. EER prepared a working document in 1980, known as the "Measurements Protocol," to define the measurement requirements for the development and demonstration of low-NO_x burners. This Measurements Protocol documented measurement methods and calibration procedures, and specified measurements for routine and detailed characterization of test conditions. Since the initiation of the project and the preparation of the Measurement Protocol, the EPA instituted a rigorous quality assurance/quality control (QA/QC) program which EER has followed. Specifically, EER has successfully established standard operating procedures for its test facilities based on the QA plans from its EPA contracts, which include 68-02-3913, 68-02-3916, 68-02-3947, and 68-02-4205. Due to the importance of this project, EER adopted a QA/QC program for this project following the requirements established in these QA plans.

Specific Quality Assurance objectives adopted for this program are outlined in Table A-1. These objectives were based on the precision and accuracy levels achievable by the selected measurement methods and consistency with established EER QA/QC procedures. Table A-2 lists the sampling procedures for each measurement. The procedures are standard EPA, ASTM, or other recognized methods. The QA procedures utilized during this program can be divided into routine and system verification checks:

Routine

- Air Flow Distribution
- Air Preheat and Combustor Wall Temperature

TABLE A-1. PROGRAM OBJECTIVES FOR MEASUREMENT PRECISION, ACCURACY, AND COMPLETENESS

Parameters	Measurement Methods	Reference	Precision: Relative Standard Deviation (%)	Accuracy (%)	Completeness (%)

- Gas Phase Species--Continuous Monitoring
- Pretest Oil Check
- Fuel Size Distribution
- Particulate Samples
- Time Limitation of Valid Data

System Verification

- Venturi Flowmeter Calibrations
- Instrument Performance Tests

The incorporation of the QA procedures into the test plan ensured the documentation and collection of quality data resulting in verifiable and more accurate results and conclusions.

Table A-3 summarizes the precision and accuracy results of key measurements determined following established EER QA procedures. The accuracy results are all within established EER QA goals and precision within limits for the principal measurements. These results are presented for sets of tests which began in October 1984 and ended in June 1986. Since all the work was done using the same equipment, verification of the measurement equipment was completed periodically (about every 6 months) rather than for each particular burner test series. Chronological test periods for each burner were:

60 x 10^6 Btu/hr	DMB	10/2/84 - 11/1/84
120 x 10^6 Btu/hr	Circular	2/28/85 - 3/26/85
120 x 10^6 Btu/hr	DMB	4/15/85 - 5/11/85
80 x 10^6 Btu/hr	DRB	8/13/85 - 9/17/85
80 x 10^6 Btu/hr	HNR	9/20/85 - 10/4/85
80 x 10^6 Btu/hr	XCL	10/8/85 - 10/29/85
80 x 10^6 Btu/hr	XCL	2/11/86 - 3/24/86

TABLE A-3. SUMMARY OF PRECISION AND ACCURACY

Measurement	Burner Configuration(s)										Goals

Notes: [1]Precision and Accuracy given as percent.

[2]NA--Relative accuracy tests not performed during this period.

Modified 60 x 10^6 Btu/hr	DMB	5/19/86 - 6/2/86
60 x 10^6 Btu/hr	DRB	6/13/86 - 6/17/86

In addition during this period, tests were conducted using the same LWS facility for:

B&W P.O. 580244 DM	6/4/85 - 7/15/85
EPA Contract 68-02-4205	11/27/85 - 1/16/86
B&W P.O. 635-0A008408 DM	4/7/86 - 4/23/86

The following subsections discuss each of the QA procedures and results for the specific measurements.

A.2 Routine QA Procedures

Routine calibrations and checks were performed on a daily basis to ensure that test data would be accurate, representative, and reproducible. Daily calibrations included air flow indication and flue gas analyzers. Other daily checks included verification of thermocouple operation, system oxygen balance while firing the oil igniter, pulverized coal size distribution, and time averaged valid data.

A.2.1 Air Flow Distribution

The flow rate and distribution of combustion air among the burner passages during the Distributed Mixing Burner evaluation was determined by direct measurement of the air flow rate to each passage using 18-inch venturi flowmeters. During the Second Generation Low NO_x burner development tests, however, a common windbox was used to contain the multiple secondary air passages because of the proprietary nature of the new B&W commercial burner designs. Thus, no direct measurement of air flow distribution was possible.

The venturi flowmeters were calibrated and checked immediately prior to each test series using a standard pitot tube. During testing, the pressure drop across each venturi meter was continuously monitored using low pressure differential electronic transducers. Each transducer was calibrated manually prior to and immediately after testing each day at pressure differentials of 0.0 and 6-inch H_2O. These pressure differentials represent zero and spanning over the typical operating range of the venturi flowmeters. A liquid manometer is used as the calibration standard.

The calibrations are documented daily on standard forms, such as shown in Table A-4 for a typical test day. The transducers were calibrated within their linear range with 1.0 mV response = 3-inch H_2O pressure differential. From these calibrations, the precision and accuracy of the air flow measurements were calculated. Table A-5 summarizes the zero and calibration drift of the venturi flowmeter transducers for each test series during the test program from October 1984 to June 1986.

A.2.2 Air Preheat and Combustor Wall Temperature

Type K (Chromel/Alumel) thermocouples were used to monitor the combustion air and furnace wall temperatures. ASTM Standard E231-77 specifies that the standard limit of error for Type K commercial thermocouples be $\pm 2^{o}C$ or ± 0.75 percent between 0^{o} and 1250^{o}. To assure that the thermocouples were functioning during testing, a continuous output of the temperatures was displayed on the computer data acquisition printout. In case of thermocouple malfunction, the damaged TC was immediately replaced. If, due to location restrictions, it was not practical to replace the TC while testing, it was replaced prior to the next day of testing.

A.2.3 Gas Phase Species

The exhaust gas phase species composition was measured using the LWS laboratory sampling system as outlined in Figure A-1. Flue gas was sampled immediately upstream of the LWS system SO_x and particulate scrubber ensuring that the flue gas sample was representative of the furnace effluent. A

Figure A-1. LWS Sample Train

single sample probe which draws from the center of the duct was used. All materials in contact with the sample gas are limited to glass, stainless steel, Teflon, and a small amount of Kel-F (valve seals) since these materials have been demonstrated as essentially nonreactive to the gases measured over the temperature range involved in this system.

Table A-6 lists the continuous gas analyzers used during these tests. To ensure accuracy, the instruments are operated according to EPA Performance Standards 2 and 3. Each instrument was calibrated with three certified gases; a zero gas and two span gases, at approximately 50 and 90 percent of scale. To increase accuracy and precision, the instruments were calibrated approximately every 2 hours during the test day. The instrument calibrations included electronically calibrating the instrument response to the data logger and the strip chart recorder, simultaneously. This ensured that the instrument, computer printout, and the strip chart were in agreement. The calibrations were documented in a calibration log, such as the example shown as Table A-7 as well as the computer printout and strip chart. This log provided data to evaluate the calibration drift of each instrument for each day of testing. Generally, if the calibration drift exceeded 4 percent during a calibration interval, the valid data obtained during that period was corrected for drift.

A.2.4 Pretest Oil Check

A pretest oil check was completed daily, prior to switching the system to coal. The oil check is used to warm up the system and as a QA check on the overall LWS process system. The oil check is a ratio between the calculated and measured load. The calculated load is a theoretical determination based on the heating value of the fuel oil and the measured oil flow rate. It is independent of the air flow system. The measured load is a function of the O_2 concentration measured in the exhaust, and the air and fuel flow rates. The resultant ratio indicates the overall accuracy of the measurement system: transducers, continuous monitoring instruments, temperatures, and fuel flow rate. The difference between the calculated and

Span Drift (%) - $\frac{S_i - S_f}{G_s}$		0	.0001	.00006											

measured load had to be less than 10 percent in order to proceed with testing.

Summaries of the daily oil checks throughout the test program from October 1984 to June 1986 are shown in Figures A-2 through A-6. The data is shown as trend graphs for the following test periods:

Figure A-2	60 x 10^6 Btu/hr DMB	Oct - Dec 1984
Figure A-3	120 x 10^6 Btu/hr DMB and Circular Burner	Feb - May 1985
Figure A-4	Second Generation Low NO_x Burners	Aug - Oct 1985
Figure A-5	Modified 80 x 10^6 Btu/hr XCL	Feb - Mar 1986
Figure A-6	Modified 60 x 10^6 Btu/hr DMB and 60 x 10^6 Btu/hr DRB	May - June 1986

Table A-8 further summarizes this data in terms of accuracy and precision of the measurement system as determined by oil checks for the entire program.

The coal input feed rate is calculated using an oxygen balance and also a weigh belt feeder. The oil check oxygen balance verifies that the calculation of the coal firing rate is justified. The weigh belt feeder also serves to confirm the calculation. The load cell of the feeder has an accuracy of $\pm$0.1 percent. However, it is necessary to calibrate the load cell dynamically and adjust the electronic set points according to the manufacturer's specification. The feeder was calibrated prior to the test series and during the tests as necessary after maintenance or repair.

A.2.5 Coal Size Distribution

The coal fineness affects the combustion performance of the burner; therefore, it was necessary to determine the coal fineness daily. The coal sample was drawn isokinetically according to the procedures outlined in ASTM Method D197 and the ASME Performance Test Code for Coal Pulverizers. The coal sample probe is shown in Figure A-7. An isokinetic sample is drawn by a vertical and horizontal traverse of the coal pipe at a sample location downstream of the pulverizer. A sample was taken daily for each coal type and firing rate. The recovery rate as specified by the method must be 100 percent $\pm$10 percent. After each sample the recovery rate was calculated. Table A-9 shows an example of the recovery rate during the tests. If the recovery rate was not within the limits, another sample was taken if operating conditions allowed. After verifying a recovery rate of 100 $\pm$ 10 percent, the sample was analyzed for size distribution.

A.2.6 Valid Data Acquisition

The outputs of all continuous instrumentation (flow rates, temperatures, and emissions) are converted to electrical signals, put into digital notation, and supplied to a Hewlett Packard computer. The computer processes this data and provides a real-time indication of input and output parameters. As a QA procedure, during a given test condition, valid data points are recorded which summarize that test. The valid data points yield average inputs and outputs, by manually inputting the gaseous concentrations. In addition, temperatures and flow rates are corrected if required to ensure that the results of the specific test includes only valid data and conditions.

A.3 System Verification Procedures

During this test program, system verification procedures that were performed included venturi flowmeter calibrations and instrument performance tests. The accuracy and precision of both air flow and the concentrations of exhaust gas components are essential to achieving quality data.

A.3.1 Venturi Flowmeter Calibration and Leak Checks

Calibrations of the venturi flowmeters were performed prior to the start of testing. The relationship between the air flow rate and pressure drop across the venturi can be expressed as:

$$(A\text{-}1) \quad Q = K \left(\frac{\Delta P}{T}\right)^{1/2}$$

where: Q = mass flowrate through the venturi (scfm)

P = pressure drop across the venturi (in H_2O)

T = absolute air temperature (^oR)

K = calibration constant

Calibrations were conducted for each venturi over a range of air flow rates, with the data reduced to the form of equation (A-1). These calibrations were incorporated into the data acquisition program used for this program. Records of the calibrations are maintained at EER.

The air flow rates measured by the venturis in the LWS system are remotely monitored. Pressure taps and thermocouples are mounted on each venturi, with the pneumatic tubing and thermocouple lead wire run into the LWS control room. Because of the environment of heat and moisture surrounding the venturis during testing, leak checks of the pneumatic tubing from the venturi to pressure transducers in the control room are conducted periodically during the test program.

A.3.2 Instrument Performance Tests

The LWS continuous monitoring system is operated according to EPA Specification 2 and 3. These specifications include instrument performance test guidelines. As part of the QA procedures applied to this test program,

instrument performance tests were conducted periodically during the test program from October 1984 to June 1986. The results of instrument tests for each test series in this program are summarized as follows:

Table A-10	60 x 10^6 Btu/hr DMB	Oct - Dec 1984
Table A-11	120 x 10^6 Btu/hr DMB and Circular Burner	Feb - May 1985
Table A-12	Second Generation Low-NO_x Burners	Aug - Oct 1985
Table A-13	Modified 80 x 10^6 Btu/hr XCL Burner	Feb - Mar 1986
Table A-14	Modified 60 x 10^6 Btu/hr DMB and 60 x 10^6 Btu/hr DRB	May - June 1986

The relative accuracy was determined by comparing the instrument values to values obtained using EPA Reference Methods. There is currently no performance specification for the CO monitor or standard reference method for CO determination. Therefore, relative accuracy could not be determined for the CO monitor. However, the 2-hour drift test was conducted in accordance with the guidelines for the other analyzers. Since the same facility and instrumentation were used throughout the duration of, the instrument performance tests of the analyzers were conducted periodically rather than for each burner test series. The relative accuracy of the continuous analyzers for O_2, CO_2, NO_x, and SO_2 is summarized for this test program in a quality control chart, Figure A-8. Throughout the test period, October 1984 to June 1986, the instruments were all within the relative accuracy goal.

The O_2, CO_2, and NO_x instruments were within the specification for zero and calibration drift for all test series conducted during the program.

Figure A-8. Continuous gas analyzer relative accuracy control chart.

During the Second Generation Low NO_x burner tests in August - October 1985, the CO analyzer zero and calibration drift were slightly higher than that allowed for the other instruments. This is probably related in part to the high sensitivity of the instrument at high span values and in part to inherent problems with drift in NDIR instruments associated with temperature fluctuations.

During the tests of the 60 x 10^6 Btu/hr DMB in the insulated LWS configuration, the calibration drift for the SO_2 instrument was higher than that allowed in the specifications. This is probably due in part to the high sensitivity of the SO_2 instrument. To compensate for the slightly higher calibration drift, the SO_2 analyzer was calibrated more frequently and adjusted as required more often than the 2-hour recommendation. The results of the zero and calibration drift test were also higher than the specification during testing of the modified 80 x 10^6 Btu/hr XCL burner conducted in 1986. Because no sorbent injection tests for SO_2 control were done during this test series, the SO_2 instrument was not essential for any valid data pertaining to the test program and SO_2 emission documentation.

The calibration error determines the linearity of the instruments. Although it is no longer required by the EPA as a performance test for continuous monitors, EER still uses this test to check the linearity of its instruments before each test series. All of the results of the tests are within the specifications previously set by the EPA for this performance test.

APPENDIX B

DMB EVALUATION VALID DATA

This appendix includes all valid test data obtained during the DMB Evaluation program. The data is presented for each burner configuration tested:

- 120×10^6 Btu/hr B&W Circular Burner
- 60×10^6 B&W Dual Register Burner
- 60×10^6 Btu/hr Distributed Mixing Burners
- 120×10^6 Btu/hr Distributed Mixing Burner

The data presented are computer listings with headings at the top of the page describing the formatted numbers below. The formatting of the data was designed for use by the test engineer to present all data characterizing each test condition as completely as possible. This results in a very dense packing of information and much abbreviation. Some of the important data in a typical computer list, shown on the following page, are explained below.

A) SYSTEM--represents the test facility configuration employed. Specifically, the EPA Large Watertube Simulator (LWS) was used for all tests in one of two configurations, its baseline configuration denoted by LWS or with additional insulation LWS-INS.

B-D) The headings B-D provided a description of the burner configuration being tested. These headings varied slightly for each burner. The different headings include:

TER DIA--"Tertiary diameter" used for all Distributed Mixing Burners. The diameter of the tertiary air ports is given in inches.

SPREADER--This describes the design of the coal nozzle device being used in the burner. In this program, this device was found to be critical to the performance of the burners and a large number of designs were evaluated.

OFA LOCATN--For some of the burners tested "overfire air" ports were used for staging the combustion process and/or injection of sorbent materials for SO_2 control. Three sets of overfire air ports were available on the LWS:

"Lower" - 8 ft above burner centerline

"Middle" - 19 ft above burner centerline

"Upper" - 23 ft above burner centerline

OFA CONFGN--This heading was used to describe the "overfire air port configuration status, namely open or closed. This heading was used for the Circular Burner tests.

E) OIL CHECK--Represents the standard procedure of closing an oxygen balance while firing a measured oil flow compared to the firing rate calculated based on oil composition, measured O_2 in the flue gas, and air flow rate measured with venturi flowmeters. The value of 2.34 for the data shown signifies that the O_2 balance was within 2.34 percent. The maximum deviation tolerable is 10 percent. This procedure is described further in Appendix A.

F) OIL, %, LOAD--Used only when oil is fired during startup. "OIL %" is the reading from a calibrated oil rotameter in percent of full

scale. "OIL LOAD" is the firing rate calculated from the rotameter reading in 10^6 Btu/hr.

G) LOAD, MBTU/HR, CALC, MEAS--Represents two methods of firing rate calculation. "CALC," the upper value (61.4), is the overall coal firing rate in 10^6 Btu/hr based on an oxygen balance derived from the fuel composition, air flow rate, and oxygen composition in the flue gas. "MEAS," the lower value (62.0), is the firing in 10^6 Btu/hr based on the feed rate of raw coal to the pulverizer and the higher heating value of the raw coal. The calculated firing rate is generally used since the varying moisture content of the raw coal contributes to significant error.

H) TA SCFM--represents the theoretical air requirement in scfm for stoichiometric combustion of the calculated firing rate.

I) Item I lists the air flow in scfm through each venturi flowmeter supplying the test burner. PRIM represents the primary air venturi flowmeter. The venturi flowmeters designated V-2 through V-5 supply the burner windbox and tertiary air ports. Larger burners, the 120 x 10^6 Btu/hr Circular burner and DMB, utilized more air ducts and venturi flowmeters to supply sufficient air flow. In the example, venturi V-6 supplied air flow to a separate oil burner and is not used when firing coal.

J) Item J lists the air temperatures in ^{o}F at the corresponding venturi flowmeters in I above.

K) Item K represents the "TOTAL" combustion air flow in scfm measured by the venturi flowmeters in Item I.

L) Item L calculates the air flow through each burner passage from the corresponding venturi flowmeters described in I. Below L are listed the air temperatures in ^{o}F and the actual air velocity in ft/sec for each burner passage.

M) Item M lists the stoichiometric ratio (SR) for each burner passage. These are listed cumulatively, which means that the fractional stoichiometric air from each passage is added to yield an overall stoichiometry for each zone.

N) Item N presents the emissions measured by the continuous monitors and include O_2, CO, CO_2, NO as NO_x, and SO_2. The top line lists the measured values on a dry basis. Below are values corrected to both 0% O_2 and 3% O_2, for easy reference. During sorbent injection, SO_2 capture is calculated based on SO_2 emissions with and without sorbent injection.

Lines O,P,Q,R list additional data to describe the test condition. The lines vary slightly for each burner, but each item is generally self-descriptive. The items from the example are briefly described here.

O) KTRON lists the coal feed rate set set point in lb/hr. The burner settings are listed for the adjustable parameters: SLEEVE is the position of the inner secondary air damper in inches from baseline position, IN REG is the outer secondary air register vane position, SPREADER is the position of the coal nozzle device from its baseline position. Pressure differential across the burner passages are listed for the inner secondary, PWB (in), and outer secondary, PWB (out). The furnace pressure and pressure drop across the coal nozzle are also listed.

P) This line lists a number of additional temperatures including primary air temperatures going into and coming out of the pulverizer; air temperatures in the inner and outer secondary windboxes; temperature of flue at the flue gas sampling location; temperatures from an array of 6 thermocouples located in the furnace exit; and a high velocity thermocouple (or suction pyrometer--"sp") at the furnace exit.

Q) Line Q contains data to characterize sorbent injection conditions when applicable, including sorbent feed rate in lb/hr, sorbent jet velocity at the injection nozzle, sorbent transport air flow, and Ca/S molar ratio. The last item in this line is a manually entered comment, or note, for the test engineer's reference.

R) This line identifies the test condition valid data point, elapsed time used to average the data in minutes, and locates the point on the computer data tape for later use.

APPENDIX B.1

120 x 10^6 Btu/HR CIRCULAR BURNER VALID DATA SUMMARY

APPENDIX C

SECOND GENERATION LOW NO_X BURNER VALID DATA

This appendix includes all valid test data obtained during the tests of B&W Second Generation Low NO_X burners. The burners tested in this part of the project were:

- 80 x 10^6 Btu/hr B&W Dual Register Burner
- 80 x 10^6 Btu/hr Babcock Hitachi NR Burner
- 80 x 10^6 Btu/hr B&W XCL Burner

The data presented are computer listings with headings at the top of the page describing the formatted numbers below. The computer list for these tests is essentially the same as for the DMB Evaluation in Appendix B with minor variations that are specific to the burner configurations. An example of a typical computer list is shown on the following page. Explanation of the principle differences from the DMB computer lists are discussed below.

A) NOZ'L DES--represents the coal "nozzle design." During the Second Generation burner tests, several coal nozzle configurations were evaluated, including: the baseline nozzle (BASELINE), flame stabilizing ring (FSR), DeNO_X stabilizer insert (DNS), and an expanded nozzle design (EXPANDED).

B) SEC.CONFGN--represents the "secondary configuration" of the burner throat. The two secondary air passage designs evaluated were the baseline (BASELINE) configuration and an air separation plate (ASP) or baffle between the inner and out secondary air passages.

C) SPREADER--As for the DMB Evaluation, this describes the design of the coal spreading device located at the end of the coal nozzle. A

number of designs were evaluated for each burner and this part of the heading briefly described the design being evaluated.

D) For the Second Generation burners, the air flow distribution between the inner and outer secondary air passages were considered proprietary by B&W. The flow rates and velocities shown in these data lists should be considered only nominal values for an estimated distribution. In the case of the XCL burner, pressure differentials from pitot grids in the inner and outer secondary air passages were included as indicators to flow distribution. The calibration of the pitot grids and thus the significance of the values were retained by B&W.

E) Line E describes the burner settings, system pressures, and primary air temperature at the outlet of the pulverizer. Each burner had similar burner adjustments, including: secondary air sleeves (dampers); coal spreaders or comparable devices; and inner and outer swirl vanes, either in a radial cascade register or axial spin vanes. Key system pressures included windbox to furnace differential; a third pitot grid for the XCL only; furnace pressure or draft; and the pressure drop across the coal nozzle.

F) Line F lists a series of system temperature indications, including: windbox air temperatures at two locations, TWB (in) and TWB (out); flue gas temperature at the gas sampling location in the exhaust duct; flue gas temperatures from an array of 6 non-aspirated thermocouples at the furnace exit; and high velocity thermocouple measurements (suction pyrometers) at several elevations in the furnace. EXIT (27') is located 27 ft above burner centerline at the furnace exit, LWS (8') is 8 ft above burner centerline, LWS (13') is 13 feet above burner centerline, and LWS (19') is 19 ft above burner centerline.
